

# Learning in Bayes Nets

**Mausam**

(Based on slides by Stuart Russell,  
Subbarao Kambhampati, Dan Weld)

# Parameter Estimation

- Learn all the CPTs in a Bayesian Net
- Data → Model → Queries
- Key idea: counting!

# Burglars and Earthquakes

- Bad idea to have prob as 0 or 1
- stumps Gibbs sampling
  - low prob states become impossible

# Solution: Smoothing

- Why?
  - To deal with events observed zero times.
  - “event”: a particular ngram
- How?
  - To shave a little bit of probability mass from the higher counts, and pile it instead on the zero counts
- Laplace Smoothing/Add-one smoothing
  - assume each event was observed at least once.
  - add 1 to all frequency counts
- Add  $m$  instead of 1 ( $m$  could be  $>$  or  $<$  1)

# Counting w/ Smoothing

$\bar{e},\bar{b}$	$\sim 0.01$

# ML vs. MAP Learning

- ML: maximum likelihood (what we just did)
  - find parameters that maximize the prob of seeing the data  $D$
  - $\operatorname{argmax}_{\theta} P(D | \theta)$
  - easy to compute (for example, just counting)
  - assumes uniform prior
- Prior: your belief before seeing any data
  - Uniform prior: all parameters equally likely
- MAP: maximum a posteriori estimate
  - maximize prob of parameters after seeing data  $D$
  - $\operatorname{argmax}_{\theta} P(\theta | D) = \operatorname{argmax}_{\theta} P(D | \theta) P(\theta)$
  - allows user to input additional domain knowledge
  - better parameters when data is sparse...
  - reduces to ML when infinite data

## Example

Suppose there are five kinds of bags of candies:

10% are  $h_1$ : 100% cherry candies

20% are  $h_2$ : 75% cherry candies + 25% lime candies

40% are  $h_3$ : 50% cherry candies + 50% lime candies

20% are  $h_4$ : 25% cherry candies + 75% lime candies

10% are  $h_5$ : 100% lime candies

Then we observe candies drawn from some bag: ● ● ● ● ● ● ● ● ● ●

What kind of bag is it?   What flavour will the next candy be?

Learning

Inference

# Full Bayesian learning

View learning as Bayesian updating of a probability distribution over the **hypothesis space**

$H$  is the hypothesis variable, values  $h_1, h_2, \dots$ , prior  $\mathbf{P}(H)$

$j$ th observation  $d_j$  gives the outcome of random variable  $D_j$   
training data  $\mathbf{d} = d_1, \dots, d_N$

Given the data so far, each hypothesis has a posterior probability:

$$P(h_i|\mathbf{d}) = \alpha P(\mathbf{d}|h_i)P(h_i)$$

where  $P(\mathbf{d}|h_i)$  is called the **likelihood**

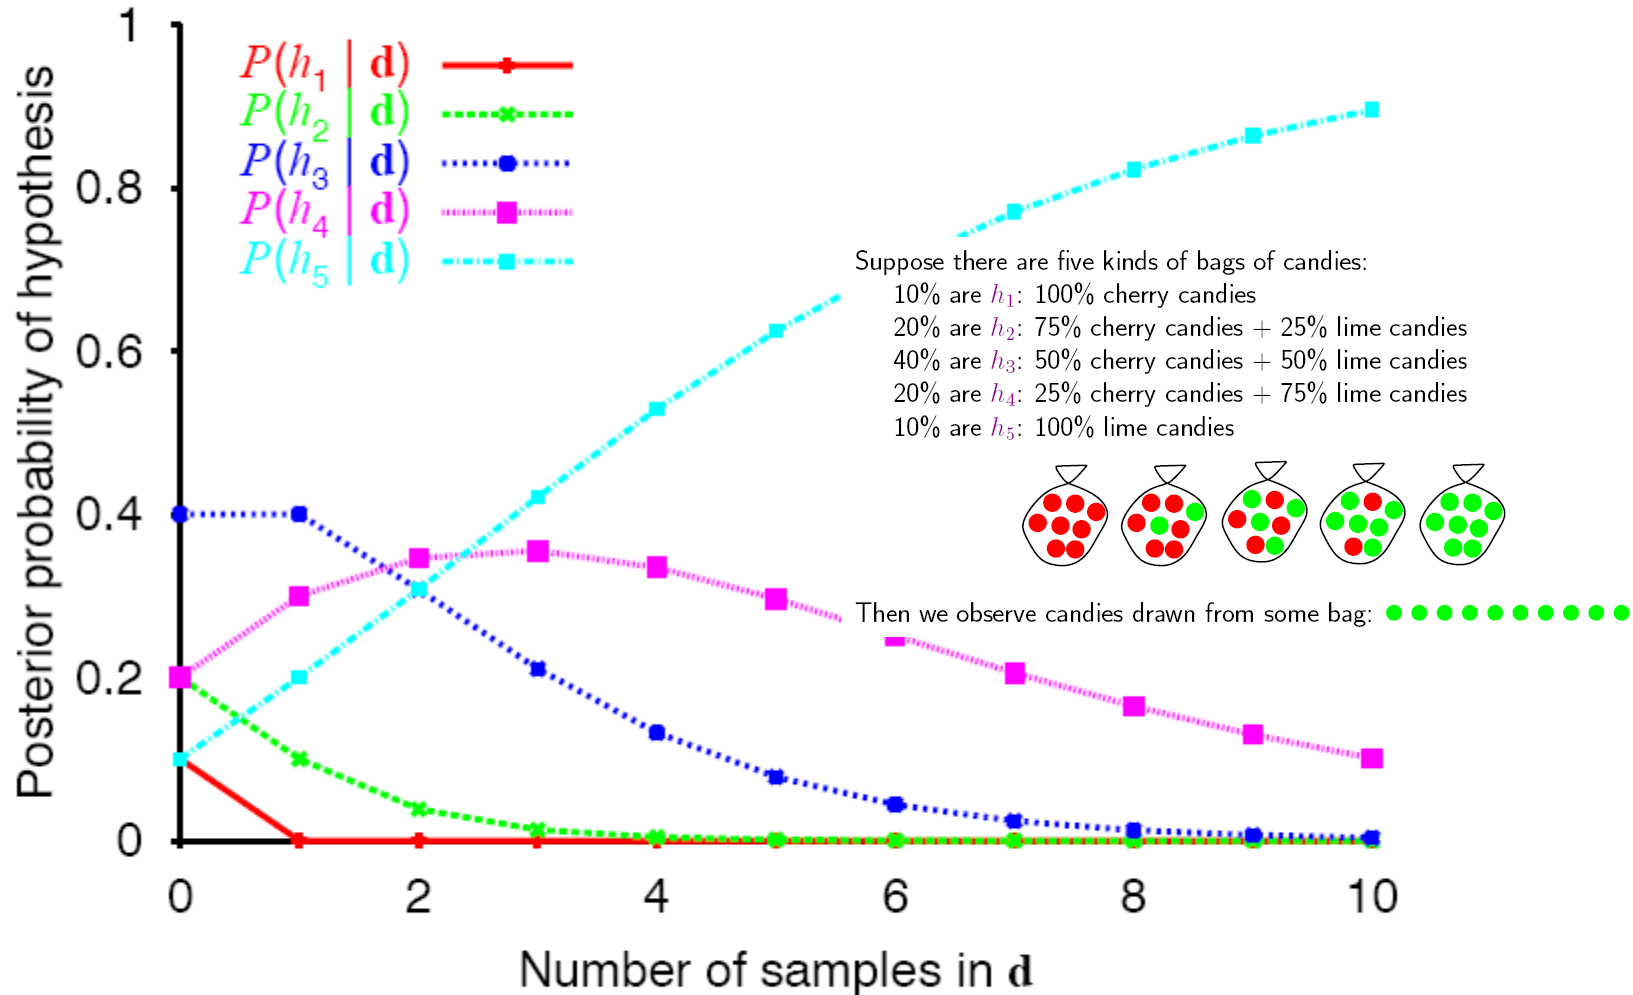

Predictions use a likelihood-weighted average over the hypotheses:

$$\mathbf{P}(X|\mathbf{d}) = \sum_i \mathbf{P}(X|\mathbf{d}, h_i)P(h_i|\mathbf{d}) = \sum_i \mathbf{P}(X|h_i)P(h_i|\mathbf{d})$$

No need to pick one best-guess hypothesis!

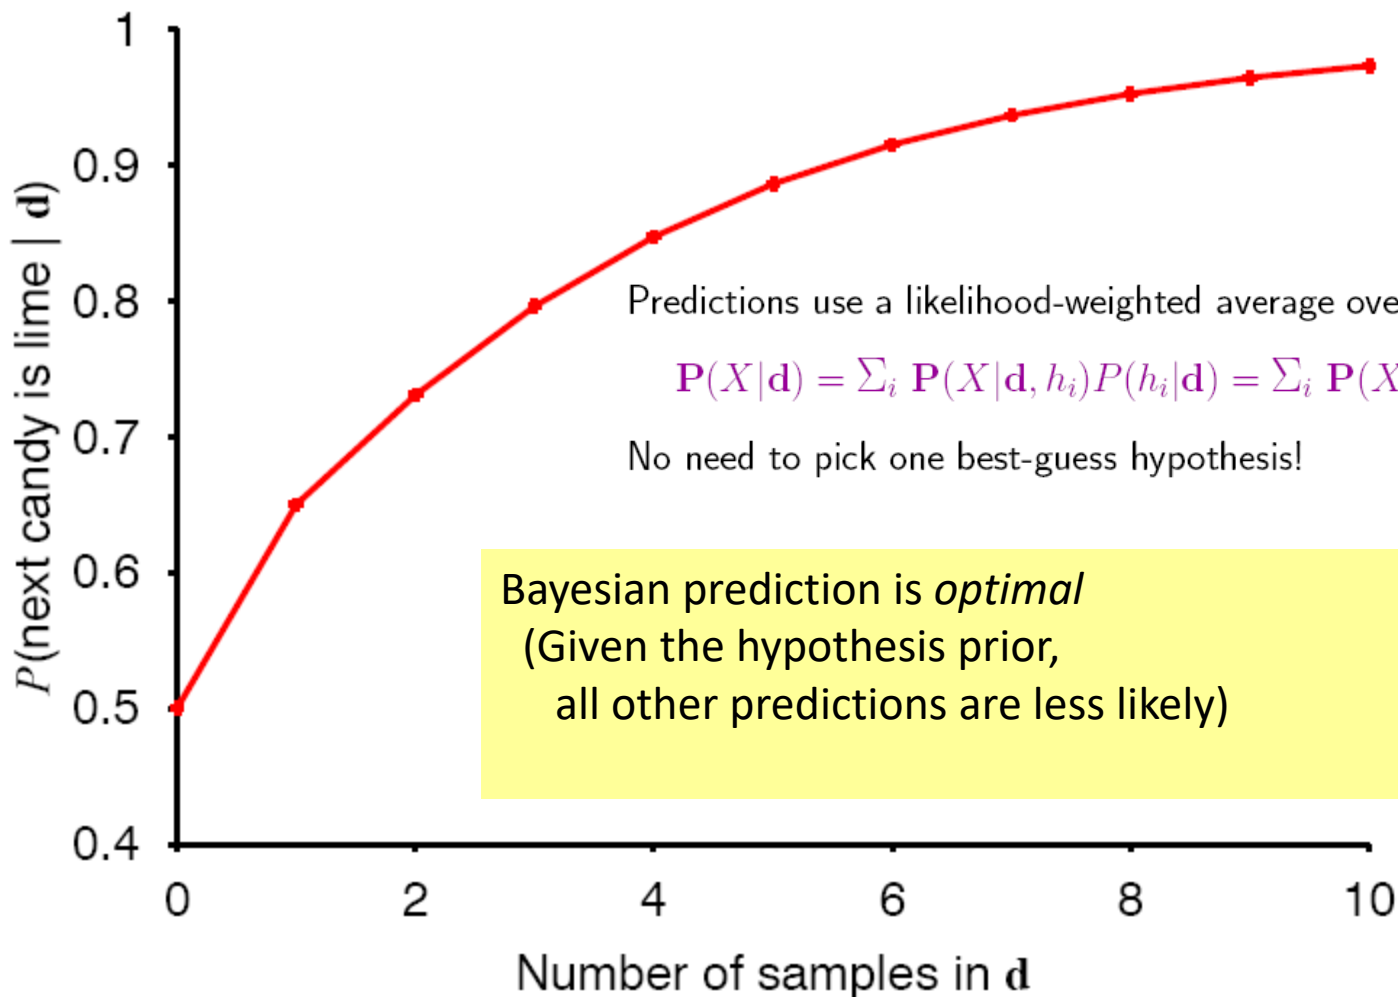

$$P(X|\mathbf{d}) = \sum P(X|h_i|\mathbf{d}) P(h_i|\mathbf{d})$$

# Posterior probability of hypotheses

True hypothesis eventually dominates...  
probability of indefinitely producing uncharacteristic data  $\rightarrow 0$

# Prediction probability

# ML vs. MAP Learning

- **ML: maximum likelihood (what we just did)**
  - find parameters that maximize the prob of seeing the data  $D$
  - $\operatorname{argmax}_{\theta} P(D | \theta)$
  - easy to compute (for example, just counting)
  - assumes **uniform prior**
- **Prior: your belief before seeing any data**
  - **Uniform prior:** all parameters equally likely
- **MAP: maximum a posteriori estimate**
  - maximize prob of parameters after seeing data  $D$
  - $\operatorname{argmax}_{\theta} P(\theta | D) = \operatorname{argmax}_{\theta} P(D | \theta) P(\theta)$
  - allows user to input additional domain knowledge
  - better parameters when data is sparse...
  - reduces to ML when infinite data

# Learning the Structure

- Problem: learn the structure of Bayes nets
- Search thru the space...
  - of possible network structures!
  - Heuristic search/local search
- For each structure, learn parameters
- Pick the one that fits observed data best
  - Caveat – won't we end up fully connected????

When scoring, add a penalty  
 $\propto$  model complexity

# Local Search

# How to learn when some data missing?

- Expectation Maximization (EM)

## Example

<b>Examples:</b>	0	1	1
	1	0	0
	1	1	1
	1	?	0

**Initialization:**  $P(B|A) =$   $P(C|B) =$   
 $P(A) =$   $P(B|\neg A) =$   $P(C|\neg B) =$

# Chicken & Egg Problem

- If we knew the missing value
  - It would be easy to learn CPT
- If we knew the CPT
  - Then it'd be easy to infer the (probability of) missing value
- But we do not know either!

## Example

<b>Examples:</b>	0	1	1
	1	0	0
	1	1	1
	1	?	0

**Initialization:**  $P(B|A) = 0$   $P(C|B) = 0$   
 $P(A) = 0.75$   $P(B|\neg A) = 0$   $P(C|\neg B) = 0$

**E-step:**  $P(? = 1) = P(B|A, \neg C) = \frac{P(A, B, \neg C)}{P(A, \neg C)} = \dots = 0$

**M-step:**  $P(B|A) =$   $P(C|B) =$   
 $P(A) =$   $P(B|\neg A) =$   $P(C|\neg B) =$

**E-step:**  $P(? = 1) =$

## Example

<b>Examples:</b>	0	1	1
	1	0	0
	1	1	1
	1	0	0

**Initialization:**  $P(B|A) = 0$   $P(C|B) = 0$   
 $P(A) = 0.75$   $P(B|\neg A) = 0$   $P(C|\neg B) = 0$

**E-step:**  $P(? = 1) = P(B|A, \neg C) = \frac{P(A, B, \neg C)}{P(A, \neg C)} = \dots = 0$

**M-step:**  $P(B|A) = 0.33$   $P(C|B) = 1$   
 $P(A) = 0.75$   $P(B|\neg A) = 1$   $P(C|\neg B) = 0$

**E-step:**  $P(? = 1) =$

# Expectation Maximization

- **Guess** probabilities for nodes with **missing values** (e.g., based on other observations)
- **Compute the probability distribution** over the missing values, given our guess
- **Update the probabilities** based on the guessed values
- **Repeat** until convergence
- Guaranteed to converge to local optimum

# Learning Summary

- **Known structure, fully observable:** only need to do parameter estimation
- **Unknown structure, fully observable:** do heuristic/local search through structure space, then parameter estimation
- **Known structure, missing values:** use expectation maximization (EM) to estimate parameters
- **Known structure, hidden variables:** apply adaptive probabilistic network (APN) techniques
- **Unknown structure, hidden variables:** too hard to solve!
